Logistics

- Read Chapter 7 and Chapter 8 from textbook
- Try out Hadoop and Spark
 - <https://hadoop.apache.org>
 - <https://spark.apache.org>
- Upcoming assignment: HW5 on Hadoop/Spark to be posted soon

Motivation: Large Scale Data Processing

- Want to:
 - Process lots of data (TB~PB)
 - Automatically parallelize across hundreds/thousands of CPUs
 - Have status and monitoring tools
 - Provide clean abstraction for programmers
 - Make this easy

MapReduce

- “A simple and powerful interface that enables automatic parallelization and distribution of large-scale computations, combined with an implementation of this interface that achieves high performance on large clusters of commodity PCs.”

Dean and Ghermanat, “MapReduce: Simplified Data Processing on Large Clusters”, Google Inc.

Typical Problem

Map

- Iterate over a large number of records
 - Extract something of interest from each
 - Shuffle and sort intermediate results
 - Aggregate intermediate results
 - Generate final output
- Key idea:** provide an abstraction at the point of these two operations

Reduce

MapReduce: Programming Model

- Process data using special **map()** and **reduce()** functions
- The **map()** function is called on every item in the input and emits a series of intermediate key/value pairs
- All values associated with a given key are grouped together
- The **reduce()** function is called on every unique key, and its value list, and emits a value that is added to the output

Programming Model

- Borrows from functional programming
- Users implement interface of two functions:
 - `map (in_key, in_value) -> (out_key, intermediate_value) list`
 - `reduce (out_key, intermediate_value list) -> out_value list`

map

- Records from the data source (lines out of files, rows of a database, etc) are fed into the map function as key*value pairs: e.g., (filename, line).
- map() produces one or more *intermediate* values along with an output key from the input.

reduce

- After the map phase is over, all the intermediate values for a given output key are combined together into a list
- `reduce()` combines those intermediate values into one or more *final values* for that same output key
- (in practice, usually only one final value per key)

MapReduce Examples

- Word frequency

MapReduce Examples

- Distributed grep
 - Map function emits `<word, line_number>` if word matches search criteria
 - Reduce function is the identity function
- URL access frequency
 - Map function processes web logs, emits `<url, 1>`
 - Reduce function sums values and emits `<url, total>`

Logistics

- HW5 out today, will be due on Tue 11/25
- HW5 is the last homework
- Final exam study guide will be posted Wednesday
- Final exam is Wednesday December 3rd
11:25am-1:25pm

MapReduce: Programming Model

MapReduce Execution Overview

1. The user program, via the MapReduce library, shards the input data

* Shards are typically 16-64mb in size

MapReduce Execution Overview

2. The user program creates process copies distributed on a machine cluster. One copy will be the “Master” and the others will be worker threads.

MapReduce Resources

3. The master distributes M map and R reduce tasks to idle workers.
 - $M ==$ number of shards
 - $R ==$ the intermediate key space is divided into R parts

MapReduce Resources

4. Each map-task worker reads assigned input shard and outputs intermediate key/value pairs.
 - Output buffered in RAM.

MapReduce Execution Overview

5. Each worker flushes intermediate values, partitioned into R regions, to disk and notifies the Master process.

MapReduce Execution Overview

6. Master process gives disk locations to an available reduce-task worker who reads all associated intermediate data.

MapReduce Execution Overview

7. Each reduce-task worker sorts its intermediate data. Calls the reduce function, passing in unique keys and associated key values. Reduce function output appended to reduce-task's partition output file.

MapReduce Execution Overview

8. Master process wakes up user process when all tasks have completed. Output contained in R output files.

MapReduce Runtime System

1. Partitions input data
2. Schedules execution across a set of machines
3. Handles machine failure
4. Manages interprocess communication

Parallelism

- `map()` functions run in parallel, creating different intermediate values from different input data sets
- `reduce()` functions also run in parallel, each working on a different output key
- All values are processed *independently*
- Bottleneck: reduce phase can't start until map phase is completely finished.

Locality

- Master program divvies up tasks based on location of data: tries to have map() tasks on same machine as physical file data, or at least same rack
- map() task inputs are divided into 64 MB blocks: same size as Google File System chunks

Fault Tolerance

- Master detects worker failures
 - Re-executes completed & in-progress map() tasks
 - Re-executes in-progress reduce() tasks
- Master notices particular input key/values cause crashes in map(), and skips those values on re-execution.
 - Effect: Can work around bugs in third-party libraries!

Optimizations

- No reduce can start until map is complete:
 - A single slow disk controller can rate-limit the whole process
- Master redundantly executes “slow-moving” map tasks; uses results of first copy to finish

MapReduce Conclusions

- MapReduce has proven to be a useful abstraction
- Greatly simplifies large-scale computations at Google
- Functional programming paradigm can be applied to large-scale applications
- Fun to use: focus on problem, let library deal w/ messy details
- Greatly reduces parallel programming complexity
 - Reduces synchronization complexity
 - Automatically partitions data
 - Provides failure transparency
 - Handles load balancing

Google's Vision

- Google GFS
